

Sample QA Audit Report

A realistic demonstration of the written, evidence-led delivery a customer receives after a fixed-scope 48-hour QA audit.

Target Northstar SaaS - demonstration environment	Audit date 04 August 2026
Author Tefik Aliu	Scope Authentication, plan upgrade, team invitation

61/100	CONDITIONAL GO	6 FINDINGS
Release readiness score	Blocker must be resolved	1 blocker - 2 high - 2 medium - 1 low

Executive conclusion

The reviewed build is not ready for an unrestricted release. The plan-upgrade flow can confirm payment while leaving the account on the previous plan. Two additional high-severity issues create duplicate requests and an unhandled invitation-token failure. Authentication smoke coverage passed, but the release should remain blocked until the subscription state is verified end to end.

Important: This report uses a fictional product and demonstration data. It is a transparent sample of delivery structure, not a claim about a real customer or live client system.

1. Prioritised findings

BLOCKER

RR-001 - Payment succeeds but account plan remains unchanged

Flow	Plan upgrade	Impact	Revenue loss, support load and immediate customer-trust risk.
Reproduction	1. Sign in as a Starter account. 2. Open Billing. 3. Select Pro. 4. Submit valid payment. 5. Observe success confirmation. 6. Refresh the account page.	Observed	The payment API returns success, but the user remains on Starter and the account endpoint continues to report the previous plan.
Recommended action	Block release. Verify state transition, webhook handling and idempotent reconciliation before retesting end to end.		

HIGH

RR-002 - Rapid double-click sends duplicate upgrade requests

Flow	Plan upgrade	Impact	Potential duplicate charges or duplicate subscription operations.
Reproduction	Enable network throttling, click Upgrade twice rapidly and inspect the network log.	Observed	Two POST requests are created before the first response disables the action.
Recommended action	Disable the action immediately, add request idempotency and cover the behaviour with an automated regression test.		

HIGH

RR-003 - Expired team invitation returns an unhandled server error

Flow	Team invitation	Impact	Users cannot recover and support receives a technical 500 response.
Reproduction	Open an expired invitation URL and attempt to accept it.	Observed	The API returns 500 and the interface shows a generic failure state.
Recommended action	Return an explicit expired-token response and provide a clear path to request a new invitation.		

MEDIUM

RR-004 - Authentication form clears user input after server validation

Flow	Authentication	Impact	Unnecessary friction and repeated data entry.
Reproduction	Submit the sign-in form with a valid email and an incorrect password.	Observed	Both fields are cleared after the server response.
Recommended action	Preserve the email field and focus the password field with a useful error message.		

MEDIUM

RR-005 - Invoice-download control has no accessible name

Flow	Billing history	Impact	Keyboard and assistive-technology users cannot identify the action reliably.
Reproduction	Inspect the invoice row using an accessibility tree or screen reader.	Observed	The icon-only control exposes no accessible label.
Recommended action	Add a meaningful accessible name and include it in the component acceptance criteria.		

LOW

RR-006 - Timezone labels are inconsistent across activity views

Flow	Account activity	Impact	Minor interpretation risk for distributed teams.
Reproduction	Compare the audit-log timestamp with the account-activity timestamp.	Observed	One view shows UTC while another uses local time without a label.
Recommended action	Standardise display and show the timezone explicitly.		

2. Coverage and automated evidence

The audit prioritises the behaviours most likely to affect revenue, trust and support load. The matrix below shows the demonstration result for each selected journey.

Journey	Manual	API	Browser automation	Result
Authentication smoke	Covered	Covered	auth-smoke.spec.ts	PASS
Plan upgrade	Covered	Covered	upgrade-plan.spec.ts	BLOCKED
Duplicate request guard	Covered	Partial	upgrade-idempotency.spec.ts	FAIL
Team invitation	Covered	Covered	invite-member.spec.ts	FAIL
Invoice accessibility	Covered	Not applicable	billing-accessibility.spec.ts	PARTIAL

Example Playwright regression check

```
test('upgraded account shows Pro plan after payment confirmation', async ({ page }) => {
  await page.goto('/billing');
  await page.getByRole('button', { name: 'Upgrade to Pro' }).click();
  await completeTestPayment(page);
  await expect(page.getByText('Payment confirmed')).toBeVisible();
  await page.reload();
  await expect(page.getByTestId('current-plan')).toHaveText('Pro');
});
```

Evidence package

Finding register Severity, impact, reproduction and next action.	Visual evidence Screenshots, video clips and relevant network output.
Automated checks Three to five focused browser or API regressions.	Release brief Blockers, conditional risks and recommended order of work.

3. Release decision and next actions

DECISION	CONDITIONAL GO - RELEASE BLOCKED BY RR-001
Required before release	Resolve subscription-state reconciliation, add idempotency protection and retest the full upgrade journey with browser and API evidence.
Recommended next	Handle expired invitation tokens explicitly, preserve authentication input after validation and add accessible names to invoice actions.
Can follow later	Standardise timezone labels across activity views.

Retest acceptance criteria

- 1 A single upgrade action creates one payment/subscription request.
- 2 The confirmed plan is visible immediately and remains correct after reload and a new session.
- 3 The account API and user interface report the same subscription state.
- 4 Expired invitations produce a controlled response and a clear recovery path.
- 5 The new regression checks pass in CI against the agreed test environment.

Scope and limits

This sample represents a functional QA and regression audit, not a penetration test, compliance certification or guarantee that every device and edge case is defect-free. Testing occurs only in explicitly authorised environments. Real client results are published only with permission.
